ATTORNEY'S DOCKET NO. MS1-906US

## **RELATED APPLICATIONS**

This application claims the benefit of U.S. Provisional Application No. 60/273,919 filed March 5, 2001, the disclosure of which is incorporated by reference herein.

## **TECHNICAL FIELD**

The present invention relates to data recording systems and, more particularly, to a system capable of recording data in various formats to perform time shifting and recording operations.

## **BACKGROUND**

Time shifting is the ability to perform various operations on a broadcast stream of data; i.e., a stream of data that is not flow-controlled. Example broadcast streams include digital television broadcasts, digital radio broadcasts, and Internet Protocol (IP) multicasts across a network, such as the Internet. A broadcast stream of data may include video data and/or audio data. Time shifting allows a user to “pause” a live broadcast stream of data without loss of data. Time shifting also allows a user to seek forward and backward through a stream of data, and play back the stream of data forward or backward at any speed. This time shifting is accomplished using a storage device, such as a hard disk drive, to store a received stream of data.

A DVR (digital video recorder or digital VCR) provides for the long term storage of a stream of data, such as a television broadcast. A DVR also uses a storage device, such as a hard disk drive, to store a received stream of data. A

1 time shifting device and a DVR may share a common storage device to store one  
2 or more data streams.

3 Existing time shifting and DVR systems operate at the transport/file format  
4 layer and support a single encoding format (typically MPEG-2). Thus, these  
5 existing systems are limited to handling streams of data encoded using the MPEG-  
6 2 format. These systems are limited in their usefulness because they cannot be  
7 used to process data streams encoded using a different format and they can only  
8 handle content that has a defined way of being stored in MPEG-2 files. If a new  
9 or modified encoding format becomes popular in the future, these systems will  
10 require modification to support a different encoding format before receiving a data  
11 stream employing the new encoding format. Alternatively, certain existing  
12 systems may require replacement with a new system capable of processing data  
13 streams using the new encoding format.

14 Fig. 1 illustrates a block diagram of an exemplary prior art time shifting  
15 system 100 capable of processing MPEG-2 broadcast data. A capture device 102  
16 receives a stream of broadcast data in the MPEG-2 format. Capture device 102  
17 provides the captured MPEG-2 data to a time shifting device 104, which stores the  
18 data on a storage device 106 in MPEG-2 format. Storage device 106 is a hard disk  
19 drive. Time shifting device 104 is also capable of retrieving stored data from  
20 storage device 106 and providing the data to a demultiplexer 108, which separates  
21 out the various components (e.g., audio and video components) in the broadcast  
22 data. The various components are then provided to a decoder 110, which decodes  
23 the data and provides the decoded data to a device (not shown) that renders or  
24 otherwise processes the decoded data. As shown in Fig. 1, system 100 is  
25

1 dedicated to processing data streams encoded using MPEG-2. System 100 is not  
2 capable of processing data streams having an encoding format other than MPEG-  
3 2.

4 The systems and methods described herein address these limitations by  
5 providing a time shifting and DVR system that is not limited to data streams  
6 having a particular format.

## 8 SUMMARY

9 The systems and methods described herein implement various time shifting  
10 and DVR functions on a broadcast data stream regardless of the encoding  
11 procedure used to create the broadcast data stream. The time shifting and DVR  
12 functions described herein can be used with a variety of different formats,  
13 including later-developed formats. The procedures and systems described herein  
14 handle the encoded content so that the procedures and systems are applicable to all  
15 data streams encoded using any encoding format.

16 In one embodiment, a broadcast data stream is received in which the  
17 broadcast data stream is encoded using any encoding format. The received  
18 broadcast data stream is demultiplexed and stored on a storage device. The  
19 broadcast data stream is then time shifted.

20 In another embodiment, a digital data stream is received and separated into  
21 components. The components of the digital data stream are stored on a storage  
22 device. A command to play back the digital data stream is received, causing the  
23 retrieval of the stored components from the storage device. The retrieved  
24 components of the digital data stream are rendered in a manner that corresponds to  
25 the play back command.

1 In a described embodiment, the storage device is a hard disk drive.

2 A particular embodiment stores the data stream in a plurality of temporary  
3 files on a hard disk drive.

4 In a particular embodiment, multiple systems retrieve the stored data stream  
5 simultaneously.

## 6 7 **BRIEF DESCRIPTION OF THE DRAWINGS**

8 Fig. 1 illustrates a block diagram of an exemplary prior art time shifting  
9 system capable of processing MPEG-2 broadcast data.

10 Fig. 2 illustrates a block diagram of a system capable of time shifting  
11 and/or recording multiple streams of broadcast data.

12 Fig. 3 illustrates a block diagram of a system having time shifting and DVR  
13 functionality.

14 Fig. 4 is a flow diagram illustrating a procedure for capturing and storing  
15 data from a received data stream.

16 Fig. 5 is a flow diagram illustrating a procedure for rendering data  
17 contained in a data stream stored on a data storage device.

18 Fig. 6 illustrates a block diagram of a system having a single capture graph  
19 and multiple rendering graphs.

20 Fig. 7 illustrates a block diagram of a system having buffering functionality  
21 to buffer an IP multicast data stream.

22 Fig. 8 illustrates the buffering of a television broadcast into multiple  
23 temporary files.

24 Fig. 9 illustrates the buffering of a television broadcast into multiple  
25 temporary files and the DVR recording of a particular television program.

1 Fig. 10 illustrates an example of a suitable operating environment in which  
2 the data recording systems and methods described herein may be implemented.

### 3 4 **DETAILED DESCRIPTION**

5 The systems and methods described herein provide for the implementation  
6 of time shifting and DVR operations that are performed independently of the  
7 format associated with the received broadcast stream of data. The time shifting  
8 and DVR operations described herein can be performed on any stream of data,  
9 regardless of the source of the data or the encoding techniques used to format the  
10 data prior to broadcast. Thus, the systems and methods can be used with a variety  
11 of different encoding formats, including future encoding formats that have not yet  
12 been developed. Any streaming and/or broadcast data, including Internet  
13 broadcasts or multicasts, from any source can be captured and processed using the  
14 procedures discussed herein. The time shifting and DVR functions described  
15 herein operate on the multimedia content substreams themselves, thereby  
16 separating the functionality of time shifting and recording from the storage format  
17 or encoding format. The methods and systems described herein operate on any  
18 type of digital data.

19 The time shifting and DVR systems and methods described herein can  
20 operate with various streaming multimedia applications, such as Microsoft®  
21 DirectShow® application programming interface available from Microsoft  
22 Corporation of Redmond, Washington. Although particular examples are  
23 described with respect to the DirectShow® multimedia application, other  
24 multimedia applications and application programming interfaces can be used in a  
25 similar manner to provide the described time shifting and DVR functionality.

1 As used herein, the term “broadcast data” refers to any stream of data, such  
2 as television broadcasts, radio broadcasts, and Internet Protocol (IP) multicasts  
3 across a network, such as the Internet, and multimedia data streams. A broadcast  
4 stream of data may include any type of data, including combinations of different  
5 types of data, such as video data, audio data and Internet Protocol (IP) data (e.g.,  
6 IP packets). Broadcast data may be received from any number of data sources via  
7 any type of communication medium.

8 Fig. 2 illustrates a block diagram of a system 200 capable of time shifting  
9 and/or recording multiple streams of broadcast data. An application 202  
10 communicates through an application programming interface (API) 204 to a time  
11 shifting and DVR device 206. Time shifting and DVR device 206 receives (or  
12 captures) data from one or more broadcast data streams, labeled Data 0, Data 1,  
13 Data 2, ... , Data N. Different data streams may originate from different data  
14 sources, contain different types of data, and utilize different formats (e.g., different  
15 encoding algorithms). One or more output data streams can be generated by time  
16 shifting and DVR device 206. These output data streams are labeled Out 0, Out 1,  
17 Out 2, ... , Out N. The output data streams may be from the same broadcast and  
18 provided to one or more users. For example, Out 0 may be providing data from  
19 the beginning of a multimedia presentation to a first user while Out 1 is providing  
20 data from the middle of the same multimedia presentation to a second user.  
21 Alternatively, the output data streams may be associated with different broadcasts  
22 stored by the time shifting and DVR device 206. For example, Out 1 may be  
23 providing data from a television broadcast to a first user while Out 2 is providing  
24 data from a multimedia presentation to a second user. In one implementation,  
25

1 each broadcast is handled by a separate instance of the device. Additional details  
2 regarding the operation of time shifting and DVR device 206 are provided below.

3 Fig. 3 illustrates a block diagram of a system 300 having time shifting and  
4 DVR functionality. All or part of system 300 may be contained in a set top box,  
5 cable box, VCR, digital television recorder, personal computer, game console, or  
6 other device. An application 302 communicates with a capture control API 304  
7 and a render control API 306. For example, application 302 may send “start”,  
8 “stop”, or “tune” instructions to capture control API 304. Similarly, application  
9 302 may send “seek”, “skip”, “rewind”, “fast forward”, and “pause” instructions  
10 to render control API 306. In one embodiment, application 302 controls various  
11 time shifting and DVR functions based on user input, pre-programmed  
12 instructions, and/or predicted viewing habits and preferences of the user.

13 Capture control API 304 communicates with a capture graph 308, which  
14 includes a capture module 310, a demultiplexer 312, and a DVR stream sink 314.  
15 Capture graph 308 is a type of DirectShow<sup>®</sup> filter graph that is associated with  
16 broadcast streams. DirectShow<sup>®</sup> is a multimedia streaming specification  
17 consisting of filters and COM interfaces. DirectShow<sup>®</sup> supports media playback,  
18 format conversion, and capture tasks. DirectShow<sup>®</sup> is based on the Component  
19 Object Model (COM). A filter is a unit of logic that is defined by input and output  
20 media types and is configured and/or queried via COM interfaces. A filter graph  
21 is a logical grouping of connected DirectShow<sup>®</sup> filters. Filters are run, stopped,  
22 and paused as a unit. Filters also share a common clock.

23 Capture graph 308 is a type of DirectShow<sup>®</sup> filter graph that is associated  
24 with broadcast streams. Capture module 310 receives broadcast data streams via a  
25 bus 316, such as a universal serial bus (USB). The broadcast stream received by

1 capture module 310 is provided to demultiplexer 312, which separates the  
2 broadcast stream into separate components, such as a video component and an  
3 audio component. The separate components are then provided to DVR stream  
4 sink 314, which communicates with a data storage subsystem 322 through a data  
5 storage API 318. Data storage subsystem 322 includes one or more data storage  
6 devices 320 for storing various information, including temporary and permanent  
7 data associated with one or more broadcast streams.

8 Render control API 306 communicates with a render graph 324, which  
9 includes a DVR stream source 326, a video decoder 328, a video renderer 330, an  
10 audio decoder 332, and an audio renderer 334. Render graph 324 is another type  
11 of DirectShow<sup>®</sup> filter graph that is associated with broadcast streams. DVR  
12 stream source 326 communicates with data storage subsystem 322 through data  
13 storage API 318 to retrieve stored broadcast stream data from data storage device  
14 320. The video component of the data retrieved by DVR stream source is  
15 provided to video decoder 328 and the audio component of the data is provided to  
16 audio decoder 332. Video decoder decodes the video data and provides the  
17 decoded video data to video renderer 330. Audio decoder 332 decodes the audio  
18 data and provides the decoded audio data to audio renderer 334. Video renderer  
19 330 displays or otherwise renders video data and audio renderer 334 plays or  
20 otherwise renders the audio data.

21 Fig. 4 is a flow diagram illustrating a procedure 400 for capturing and  
22 storing data from a received data stream. For example, the procedure for  
23 capturing a data stream may be performed by capture graph 308 (Fig. 3). Initially,  
24 procedure 400 determines whether a “start” command has been received (block  
25 402). Such a command may be received, for example, from application 302 based

1 on a user input or a pre-programmed command. If a “start” command is not  
2 received, the procedure returns to block 402. If a “start” command is received, a  
3 capture module receives a data stream (block 404) and a demultiplexer separates  
4 the data stream components (block 406). The data stream components may  
5 include, for example, audio data and video data. Next, a DVR stream sink writes  
6 the data stream components to a data storage API (block 408). Additionally, the  
7 DVR stream sink may write certain attributes and other data to the data storage  
8 API along with the data stream components. The data storage API then stores the  
9 data stream components to a data storage device for later retrieval.

10 At block 410, procedure 400 determines whether a “stop” command has  
11 been received. If so, the capture module stops receiving the data stream (block  
12 412). The procedure then returns to block 402 to await another “start” command.  
13 If a “stop” command is not received, the procedure returns to block 404 to  
14 continue receiving and processing the data stream.

15 Fig. 5 is a flow diagram illustrating a procedure 500 for rendering data  
16 contained in a data stream stored on a data storage device. Initially, procedure 500  
17 determines whether a playback control command has been received (block 502).  
18 Playback control commands may include “pause”, “play”, “fast forward”,  
19 “rewind”, “slow motion forward”, “slow motion backward”, “seek”, “skip  
20 forward”, “skip backward”, and other commands that affect the rendering of the  
21 data stream. If a playback control command is not received, the procedure  
22 branches to block 502 to await a playback control command. If a playback control  
23 command is received, the DVR stream source reads the data stream from the data  
24 storage device based on the playback control command (block 504). For example,  
25 if the playback command is “play”, the DVR stream source reads data beginning

1 with the last data read, such as the data read before a “pause” command was  
2 received. If the playback command is “slow motion backward”, the DVR stream  
3 source reads data beginning at the same location, but in the reverse direction (i.e.,  
4 going backwards in time).

5 At block 506, the procedure decodes the data stream components (e.g.,  
6 decode the audio component and decode the video component). Next, the data  
7 stream components are rendered at block 508. At block 510, procedure 500  
8 determines whether a new playback control command has been received. If not,  
9 the procedure returns to block 504 to continue reading the data stream from the  
10 data storage device based on the most recent playback control command. If a new  
11 playback control command is received, the DVR stream source continues reading  
12 and processing the data stream from the data storage device based on the new  
13 playback control command (block 512). However, if the new playback control  
14 command is “pause” or “stop”, the DVR stream source stops reading the data  
15 stream until a new playback control command is received that requires reading of  
16 the data stream.

17 The rendering controls are independent of the capture controls, such that  
18 the rendering controls (e.g., pausing playback, fast-forwarding or rewinding) do  
19 not affect the capturing of the broadcast data stream. Similarly, stopping the  
20 capturing of the broadcast data stream does not alter the ability of the rendering  
21 controls to retrieve and render the previously stored data stream components.

22 Fig. 6 illustrates a block diagram of a system 600 having a single capture  
23 graph and multiple rendering graphs. An application 602 communicates with a  
24 capture control API 604 and multiple render control APIs 614, 618, and 622.  
25 Capture control API 604 communicates with a capture graph 606, which is similar

1 to capture graph 308, discussed above. Capture graph 606 stores broadcast data  
2 streams to a data storage device by communicating with a data storage API 608,  
3 which communicates with a data storage subsystem 610. Multiple render graphs  
4 616, 620, and 624 are configured to retrieve data from the data storage device by  
5 communicating with data storage API 608. Each render graph generates a  
6 different data stream (Data 0, Data 1 or Data 2) based on the playback control  
7 commands received from application 602. Each render graph 616, 620, and 624  
8 may be associated with a particular user, allowing each user to view different  
9 portions of the same broadcast data stream or to view different broadcast data  
10 streams (e.g., different television programs recorded in the storage device).

11 Fig. 7 illustrates a block diagram of a system 700 having buffering  
12 functionality to buffer an IP multicast data stream. An application program 702  
13 allows a user to control the capturing and rendering of the IP multicast data  
14 stream. The IP multicast data stream may be, for example, a data stream from an  
15 Internet radio station. In this example, delays or network congestion may affect  
16 the rate at which the IP multicast data stream is received. Thus, a data buffering  
17 system is used to buffer or “pre-load” data such that a small delay in receiving data  
18 from the Internet will not affect the audio signal produced by an audio renderer.  
19 The larger the buffer, the greater the delay that can be handled by the system  
20 before affecting the audio signal.

21 Application program 702 communicates with a capture control API 704 and  
22 a render control API 706. Capture control API 704 communicates with a capture  
23 graph 708, which includes an IP multicast receiver 712, an audio analysis module  
24 714, and a data stream sink 716. IP multicast receiver 712 receives an IP multicast  
25 data stream via the Internet or other data communication network. IP multicast

1 receiver 712 provides the received data stream to an audio analysis module 714,  
2 which marks the received data stream with attributes, such as time stamps,  
3 cleanpoint flags, and discontinuities. Additional details regarding these various  
4 attributes are discussed below.

5 Data stream sink 716 writes the received data stream (including attributes  
6 added by audio analysis module 714) to a buffer API 718, which communicates  
7 with a buffer subsystem 720. Buffer subsystem 720 includes a data buffer 722,  
8 which stores various data related to one or more IP multicast data streams.

9 Render control API 706 communicates with a render graph 710, which  
10 includes a data stream source 724, an audio decoder 726, and an audio renderer  
11 728. Data stream source 724 retrieves buffered data streams from data buffer 722  
12 by issuing commands to buffer API 718. Audio decoder 726 decodes the audio  
13 data in the retrieved data stream such that audio renderer 728 can properly render  
14 an audio signal corresponding to the retrieved data stream.

15 Time shifting and DVR recording require a backing storage device, such as  
16 a hard disk drive. Typically, data is written to one or more files on the hard disk  
17 drive. Content is written to the file and later (or concurrently), the content is read  
18 back out of the file to be decoded and rendered. This backing storage device is  
19 useful because a system's core memory is generally insufficient to temporarily  
20 store high-speed multimedia content for an arbitrary duration. A particular  
21 solution uses a ring buffer to store data received in a data stream. In this example,  
22 data is written into multiple files on the hard disk, which spreads the received  
23 content across multiple files on the hard disk drive.

24 Fig. 8 illustrates the buffering of a television broadcast into multiple  
25 temporary files on a storage device, such as a hard disk drive. The system of Fig.

1 8 represents a thirty minute logical ring buffer 802 backed by four temporary files  
2 (labeled Temp1, Temp2, Temp3, and Temp4). Ring buffer 802 communicates with  
3 the temporary files through a data storage API 804. Each temporary file has a  
4 beginning (start of file) and an end (end of file). The ring buffer consists of the  
5 four temporary files logically coupled together by the logical ring buffer 802.  
6 Each of the temporary files is accessed through the data storage API 804. The  
7 logical ring buffer 802 translates a virtual stream of data into a file and a file  
8 offset. A seek operation is performed in terms of time, so the ring buffer tracks  
9 the start time for each temporary file. When a virtual time offset is requested, the  
10 ring buffer 802 translates the virtual time offset into a file and a file time offset.

11 For example, a particular ring buffer may organize the four temporary files  
12 shown in Fig. 8 such that each temporary file stores 7.5 minutes of broadcast data.  
13 Thus, the four files that make up the logical ring buffer provide storage for thirty  
14 minutes of broadcast data. If a seek request is received to seek to twenty minutes,  
15 the system translates this request into a seek into temporary file Temp3 with a time  
16 offset of 5 minutes.

17 In the example of Fig. 8, a television broadcast stream is captured  
18 beginning at 7:05, which causes the fourth temporary file (Temp4) to fill at 7:35.  
19 At this point, the system wraps back around and continues recording with the first  
20 temporary file (Temp1), thereby overwriting the data previously stored in the first  
21 temporary file. This process continues for thirty minutes until 8:05, when the  
22 system again wraps around to continue recording at the beginning of the first  
23 temporary file.

24 The separation of the captured data into multiple temporary files is  
25 transparent to the user of the system. Additionally, the wrapping from the last

multiple file back to the first is transparent to the user and does not disrupt rendering of the broadcast data stream.

Fig. 9 illustrates the buffering of a television broadcast into multiple temporary files and the DVR recording of a particular television program. A logical ring buffer 902 communicates with a data storage API 904, which communicates with various temporary and permanent files stored on a storage device (not shown). The system of Fig. 9 uses four temporary files (Temp1, Temp2, Temp3, and Temp4) for time shifting functions, in the manner discussed above with respect to Fig. 8. Additionally, the system of Fig. 9 uses one or more program files to store programs based on DVR recording requests (e.g., a request to permanently store a particular program or series of programs).

Fig. 9 illustrates a situation in which a background recording operation is scheduled to occur between 8:00 and 8:30, which falls in the middle of a session in which a broadcast stream is being rendered and viewed (i.e., 7:45 – after 8:30). The system of Fig. 9 chains together the four temporary files and the one permanent file (Program1) to present a single recorded broadcast stream to the user of the system. The permanent file is not deleted or overwritten when the temporary files are deleted or overwritten.

In a particular embodiment, multimedia content is treated without regard to its encoding method. Instead, the multimedia content is treated as byte buffers with attributes. Components (e.g., APIs) that understand the multimedia content tag the buffers with various attributes and/or flags, such as: 1) a “cleanpoint” flag, which is applied to the first byte of the buffer, 2) a presentation time stamp applied to the first byte of the buffer, 3) a stream time stamp, which represents the time at which the first byte of the buffer is presented to the system, and 4) a discontinuity

1 flag, which indicates whether there is a connection with previously received data.  
2 A “cleanpoint” is a play-start point, and is also referred to as a “keyframe”. Some  
3 compression schemas leverage redundancy from one frame to the next. Instead of  
4 sending a complete frame, only predictive data is sent. The decoder reconstructs a  
5 complete frame based on a previously received complete frame and the predictive  
6 data. Since the predictive data is not useful without a complete frame from which  
7 to reference it, each complete frame is flagged as a “cleanpoint”. This is useful for  
8 subsequent seek requests and provides a starting point from which to resume  
9 playback. The discontinuity flag is useful in, for example, MPEG-2 because video  
10 is received as groups of pictures (GOPs) which have one reference frame and  
11 several derived frames. If a discontinuity occurs in the middle of a GOP, the  
12 decoder will discard all subsequent frames until it receives the next GOP’s  
13 reference frame.

14 When storing data to the data storage subsystem, the system translates  
15 higher-level flags and attributes to those required by the data storage API. The  
16 system then determines the specific file in the data storage subsystem that will  
17 receive the content. Finally, the content is written with the associated flags and  
18 attributes into the file via the data storage API.

19 When retrieving data from the data storage subsystem, the system  
20 maintains a context for each reader. The system determines the file that contains  
21 the data to be retrieved. The data is retrieved with its flags and attributes. The  
22 flags and attributes are then translated to those required by the higher-level  
23 multimedia layer. The read call is then completed.

24 Seeking forwards and backwards is based on a time relative to now (i.e., the  
25 current time). Based on relative time from now, the system determines the file

1 from which the data will be read. The absolute time offset is then translated to a  
2 file-specific time offset. The system then seeks, via the data storage API, to the  
3 computed time offset. The data is then retrieved using the procedure discussed  
4 above.

5 The data storage API provides the ability to perform various operations,  
6 such as:

- 7 • multiplexing multiple streams into a file (and distinguishing each  
8 stream from the others),
- 9 • ensuring that the data retrieval order matches the data storage order,
- 10 • associating a timestamp with data and retrieving the timestamp upon  
11 retrieval of the data,
- 12 • associating one or more variable-sized attributes with data and  
13 retrieving the attributes upon retrieval of the data,
- 14 • associating a generic marker with specific data and seeking to that  
15 marker,
- 16 • indexing on time and seeking to data based on that time, and
- 17 • providing support for a Digital Rights Management framework.

18  
19 In one implementation, the Windows Media SDK API, available from  
20 Microsoft Corporation of Redmond, Washington, is used as the data storage API  
21 discussed above. Additionally, data is stored in the data storage subsystem using  
22 the Advanced Streaming Format (ASF), a file format that specifies a definition for  
23 streaming media.

24 Fig. 10 illustrates an example of a suitable operating environment in which  
25 the data recording systems and methods described herein may be implemented.

1 The illustrated operating environment is only one example of a suitable operating  
2 environment and is not intended to suggest any limitation as to the scope of use or  
3 functionality of the invention. Other well-known computing systems,  
4 environments, and/or configurations that may be suitable for use with the  
5 invention include, but are not limited to, personal computers, server computers,  
6 hand-held or laptop devices, multiprocessor systems, microprocessor-based  
7 systems, programmable consumer electronics, gaming consoles, cellular  
8 telephones, network PCs, minicomputers, mainframe computers, distributed  
9 computing environments that include any of the above systems or devices, and the  
10 like.

11 Fig. 10 shows a general example of a computer 1042 that can be used in  
12 accordance with the invention. Computer 1042 is shown as an example of a  
13 computer that can perform the various functions described herein. Computer 1042  
14 includes one or more processors or processing units 1044, a system memory 1046,  
15 and a bus 1048 that couples various system components including the system  
16 memory 1046 to processors 1044.

17 The bus 1048 represents one or more of any of several types of bus  
18 structures, including a memory bus or memory controller, a peripheral bus, an  
19 accelerated graphics port, and a processor or local bus using any of a variety of  
20 bus architectures. The system memory 1046 includes read only memory (ROM)  
21 1050 and random access memory (RAM) 1052. A basic input/output system  
22 (BIOS) 1054, containing the basic routines that help to transfer information  
23 between elements within computer 1042, such as during start-up, is stored in ROM  
24 1050. Computer 1042 further includes a hard disk drive 1056 for reading from  
25 and writing to a hard disk, not shown, connected to bus 1048 via a hard disk drive

1 interface 1057 (e.g., a SCSI, ATA, or other type of interface); a magnetic disk  
2 drive 1058 for reading from and writing to a removable magnetic disk 1060,  
3 connected to bus 1048 via a magnetic disk drive interface 1061; and an optical  
4 disk drive 1062 for reading from and/or writing to a removable optical disk 1064  
5 such as a CD ROM, DVD, or other optical media, connected to bus 1048 via an  
6 optical drive interface 1065. The drives and their associated computer-readable  
7 media provide nonvolatile storage of computer readable instructions, data  
8 structures, program modules and other data for computer 1042. Although the  
9 exemplary environment described herein employs a hard disk, a removable  
10 magnetic disk 1060 and a removable optical disk 1064, it will be appreciated by  
11 those skilled in the art that other types of computer readable media which can store  
12 data that is accessible by a computer, such as magnetic cassettes, flash memory  
13 cards, random access memories (RAMs), read only memories (ROM), and the  
14 like, may also be used in the exemplary operating environment.

15 A number of program modules may be stored on the hard disk, magnetic  
16 disk 1060, optical disk 1064, ROM 1050, or RAM 1052, including an operating  
17 system 1070, one or more application programs 1072, other program modules  
18 1074, and program data 1076. A user may enter commands and information into  
19 computer 1042 through input devices such as keyboard 1078 and pointing device  
20 1080. Other input devices (not shown) may include a microphone, joystick, game  
21 pad, satellite dish, scanner, or the like. These and other input devices are  
22 connected to the processing unit 1044 through an interface 1068 that is coupled to  
23 the system bus (e.g., a serial port interface, a parallel port interface, a universal  
24 serial bus (USB) interface, etc.). A monitor 1084 or other type of display device is  
25 also connected to the system bus 1048 via an interface, such as a video adapter

1 1086. In addition to the monitor, personal computers typically include other  
2 peripheral output devices (not shown) such as speakers and printers.

3 Computer 1042 operates in a networked environment using logical  
4 connections to one or more remote computers, such as a remote computer 1088.  
5 The remote computer 1088 may be another personal computer, a server, a router, a  
6 network PC, a peer device or other common network node, and typically includes  
7 many or all of the elements described above relative to computer 1042, although  
8 only a memory storage device 1090 has been illustrated in Fig. 10. The logical  
9 connections depicted in Fig. 10 include a local area network (LAN) 1092 and a  
10 wide area network (WAN) 1094. Such networking environments are  
11 commonplace in offices, enterprise-wide computer networks, intranets, and the  
12 Internet. In certain embodiments, computer 1042 executes an Internet Web  
13 browser program (which may optionally be integrated into the operating system  
14 1070) such as the "Internet Explorer" Web browser manufactured and distributed  
15 by Microsoft Corporation of Redmond, Washington.

16 When used in a LAN networking environment, computer 1042 is connected  
17 to the local network 1092 through a network interface or adapter 1096. When  
18 used in a WAN networking environment, computer 1042 typically includes a  
19 modem 1098 or other means for establishing communications over the wide area  
20 network 1094, such as the Internet. The modem 1098, which may be internal or  
21 external, is connected to the system bus 1048 via a serial port interface 1068. In a  
22 networked environment, program modules depicted relative to the personal  
23 computer 1042, or portions thereof, may be stored in the remote memory storage  
24 device. It will be appreciated that the network connections shown are exemplary  
25

1 and other means of establishing a communications link between the computers  
2 may be used.

3 Computer 1042 typically includes at least some form of computer readable  
4 media. Computer readable media can be any available media that can be accessed  
5 by computer 1042. By way of example, and not limitation, computer readable  
6 media may comprise computer storage media and communication media.  
7 Computer storage media includes volatile and nonvolatile, removable and non-  
8 removable media implemented in any method or technology for storage of  
9 information such as computer readable instructions, data structures, program  
10 modules or other data. Computer storage media includes, but is not limited to,  
11 RAM, ROM, EEPROM, flash memory or other memory technology, CD-ROM,  
12 digital versatile disks (DVD) or other optical storage, magnetic cassettes, magnetic  
13 tape, magnetic disk storage or other magnetic storage devices, or any other media  
14 which can be used to store the desired information and which can be accessed by  
15 computer 1042. Communication media typically embodies computer readable  
16 instructions, data structures, program modules or other data in a modulated data  
17 signal such as a carrier wave or other transport mechanism and includes any  
18 information delivery media. The term "modulated data signal" means a signal that  
19 has one or more of its characteristics set or changed in such a manner as to encode  
20 information in the signal. By way of example, and not limitation, communication  
21 media includes wired media such as wired network or direct-wired connection,  
22 and wireless media such as acoustic, RF, infrared and other wireless media.  
23 Combinations of any of the above should also be included within the scope of  
24 computer readable media.  
25

1 The invention has been described in part in the general context of  
2 computer-executable instructions, such as program modules, executed by one or  
3 more computers or other devices. Generally, program modules include routines,  
4 programs, objects, components, data structures, etc. that perform particular tasks  
5 or implement particular abstract data types. Typically the functionality of the  
6 program modules may be combined or distributed as desired in various  
7 embodiments.

8 For purposes of illustration, programs and other executable program  
9 components such as the operating system are illustrated herein as discrete blocks,  
10 although it is recognized that such programs and components reside at various  
11 times in different storage components of the computer, and are executed by the  
12 data processor(s) of the computer.

13 Although the description above uses language that is specific to structural  
14 features and/or methodological acts, it is to be understood that the invention  
15 defined in the appended claims is not limited to the specific features or acts  
16 described. Rather, the specific features and acts are disclosed as exemplary forms  
17 of implementing the invention.
